Abstract

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

Abstract (Nederlands)

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

5.4 FTIR: Hydrogen content and microstructure

After measuring the transmission with FTIR, the determination of hydrogen bond concentrations can be divided into two problems:

1. Converting the transmission spectrum to an absorption coefficient spectrum.

2. Calculating bond concentrations from the integrated absorbances, by multiplying with the correct proportionality constant.

Note that the second point is not relevant for calculating the microstructure parameter R^*, because this is a ratio of integrated absorbances. Proportionality constants for the various bonds can be found in literature, and originate from other means of measuring the hydrogen content [2].

5.4.1 From transmission to absorption coefficient

Lambert-Beer law

The Lambert-Beer law cannot be used due to the multiple reflections in the wafer.

BCC method: incoherent multiple reflections

An often used method to determine the absorption coefficient from the measured transmission is commonly referred to as the BCC method [1]. The method assumes incoherent transmission in both the thin film and the substrate. It states the transmission T as a function of the film absorption coefficient α, the film thickness d, and the absorption-free transmission T_0 of the c-Si substrate:

$$T = \frac{4T_0^2 e^{-\alpha d}}{(1+T_0)^2 - (1-T_0)^2 e^{-2\alpha d}}. \tag{5.1}$$

A derivation of this equation is given in a paper by Maley [3]. In addition to assuming incoherent transmission, the equation is also strictly only true for a freely supported film [1]. By making this simplification, the model decouples the transmission of the substrate and the thin film. This is correct if the substrate has zero absorption, and if the refractive indices of the thin film and the substrate are equal. for some wavelength regions these two assumptions seem reasonable.

In general the refractive index of a-Si:H is not equal to that of the substrate: it depends on the hydrogen content C_H. This mismatch causes broad and shallow interference fringes [2].

Swanepoel has investigated the effect of thickness variation, surface roughness, and variation in refractive index on the transmission spectrum [4].
